ASYMPTOTIC BEHAVIOR OF THE MAXIMUM AND MINIMUM SINGULAR VALUE OF RANDOM VANDERMONDE MATRICES

GABRIEL H. TUCCI AND PHILIP A. WHITING

Abstract. This work examines various statistical distributions in connection with random Vandermonde matrices and their extension to d-dimensional phase distributions. Upper and lower bound asymptotics for the maximum singular value are found to be $O(\log N^d)$ and $O(\log N^d / \log\log N^d)$ respectively where N is the dimension of the matrix, generalizing the results in [21]. We further study the behavior of the minimum singular value of a random Vandermonde matrix. In particular, we prove that the minimum singular value is at most $N^2 \exp(-C\sqrt{N}))$ where N is the dimension of the matrix and C is a constant. Furthermore, the value of the constant C is determined explicitly. The main result is obtained in two different ways. One approach uses techniques from stochastic processes and in particular, a construction related with the Brownian bridge. The other one is a more direct analytical approach involving combinatorics and complex analysis. As a consequence, we obtain a lower bound for the maximum absolute value of a random complex polynomial on the unit circle. We believe that this has independent mathematical interest. Lastly, for each sequence of positive integers $\{k_p\}_{p=1}^{\infty}$ we present a generalized version of the previously discussed random Vandermonde matrices. The classical random Vandermonde matrix corresponds to the sequence $k_p = p-1$. We find a combinatorial formula for their moments and we show that the limit eigenvalue distribution converges to a probability measure supported on $[0,\infty)$. Finally, we show that for the sequence $k_p = 2^p$ the limit eigenvalue distribution is the famous Marchenko–Pastur distribution.

1. Introduction

Large dimensional random matrices are of much interest in statistics, where they play a roll in multivariate analysis. In his seminal paper, Wigner [24] proved that the spectral measure of a wide class of symmetric random matrices of dimension N converges, as $N \to \infty$ to the semicircle law. Much work has since been done on related random matrix ensembles, either composed of (nearly) independent entries, or drawn according to weighted Haar measures on classical (e.g., orthogonal, unitary, simplectic) groups. The limiting behavior of the spectrum of such matrices and their compositions is of considerable interest for mathematical physics and information theory. In addition, such random matrices play an important role in operator algebra studies initiated by Voiculescu, known now as free (non–commutative) probability theory (see [22] and [23] and the many references therein). The study of large random matrices is also related to interesting questions of combinatorics, geometry, algebra and number theory. More recently, the study of large random matrices ensembles with additional structure have been considered. For instance, the properties of the spectral measures of random Hankel, Markov and Toeplitz matrices with independent entries have been studied in [6].

In this paper we study several aspects of random Vandermonde matrices with unit magnitude complex entries and their generalizations. An $N \times L$ matrix $\mathbf{V}$ with unit complex entries is a

Vandermonde matrix if there exist values $\theta_1, \ldots, \theta_L \in [0,1]$ such that

$$\mathbf{V} := \frac{1}{\sqrt{N}} \begin{pmatrix} 1 & \ldots & 1 \\ e^{2\pi i\theta_1} & \ldots & e^{2\pi i\theta_L} \\ \vdots & \ddots & \vdots \\ e^{2\pi i(N-1)\theta_1} & \ldots & e^{2\pi i(N-1)\theta_L} \end{pmatrix} \tag{1.1}$$

(see [17] or [21] for more details). A random Vandermonde matrix is produced if the entries of the phase vector $\theta := (\theta_1, \ldots, \theta_L) \in [0,1]^L$ are random variables. For the purposes of this paper it will be assumed that the phase vector has i.i.d. components, with distribution drawn according to a measure ν which has a density $f(x)$ on $[0,1]$.

Vandermonde matrices were defined in [13] and were also called d-fold Vandermonde matrices. The case $d = 1$ are the matrices in (1.1). For $d \geq 2$, these matrices are defined by selecting L random vectors $\mathbf{x}_q$ independently in the d-dimensional hypercube $[0,1]^d$. These vectors are called the vectors of phases. Given a scale parameter N, consider the function defined by $\gamma : \{0,1,\ldots,N-1\}^d \to \big\{0,1,\ldots,N^d-1\big\}$ such that for every vector of integers $\mathbf{m} = (\ell_1, \ell_2, \ldots, \ell_d) \in \{0,1,\ldots,N-1\}^d$ the value $\gamma(\mathbf{m})$ is equal to

$$\gamma(\mathbf{m}) := \sum_{j=1}^{d} N^{j-1}\ell_j.$$

It is easy to see that this function is a bijection over the set $\big\{0,1,\ldots,N^d-1\big\}$. Now we define the $N^d \times L$ matrix $\mathbf{V}^{(d)}$ as

$$\mathbf{V}^{(d)}_{(\gamma(\mathbf{m}),q)} := \frac{1}{N^{d/2}} \exp\Big(2\pi i\langle \mathbf{m}, \mathbf{x}_q\rangle\Big). \tag{1.2}$$

For the case $d = 1$ we drop the upper index and we denote these matrices by $\mathbf{V}$, for $d \geq 2$ we denote them by $\mathbf{V}^{(d)}$.

Random Vandermonde matrices and their extended versions are a natural construction with a wide range of applications in fields as diverse as finance [12], signal processing [13], wireless communications [14], statistical analysis [3], security [18] and biology [19]. This stems from the close relationship that unit magnitude complex Vandermonde matrices have with the discrete Fourier transform. Among these, there is an important recent application for signal reconstruction using noisy samples (see [13]) where an asymptotic estimate is obtained for the mean squared error. In particular, and as was shown in [13], generalized Vandermonde matrices play an important role in the minimum mean squared error estimation of vector fields, as might be measured in a sensor network. In such networks, the parameter d is the dimension of the field being measured, L is the number of sensors and N can be taken as the approximate bandwidth of the measured signal per dimension. This asymptotic can be calculated as a random eigenvalue expectation, whose limit distribution depends on the signal dimension d. In the case $d = 1$ the limit is via random Vandermonde matrices. As $d \to \infty$ the Marchenko–Pastur limit distribution is shown to apply. Further applications were treated in [17] including source identification and wavelength estimation.

One is typically interested in studying the behavior of these matrices as both N and L go to infinity at a given ratio, $\lim_{N\to\infty} \frac{L}{N^d} = \beta$. In [17], important results were obtained for the case $d = 1$. In particular, the limit of the moments of $\mathbf{V}^*\mathbf{V}$ was proved and a combinatorial formula for the asymptotic moments was given under the hypothesis of continuous density. In [21], these results were extended to more general densities and it was also proved that these moments arise as the moments of a probability measure $\mu_{\nu,\beta}$ supported on $[0,\infty)$. This measure depends of course on the measure ν, the distribution of the phases, and on the constant β.

In [21], the behavior of the maximum eigenvalue was studied and tight upper and lower bounds for this one were found. Here we extend these results and study the maximum eigenvalue of the d-fold extended Vandermonde matrix. More specifically, we study the asymptotic behavior of the maximum eigenvalue of the matrix ${\mathbf{V}^{(d)}}^{*}\mathbf{V}^{(d)}$ and derive upper and lower bounds.

A natural question is to examine the behavior of the smallest singular value as $N\to\infty$, and this paper is one of the first to address this question. Here we restrict to the case $d=1$. On one hand, it is clear that if $L>N$ then the matrix $\mathbf{V}^{*}\mathbf{V}$ is of size $L\times L$ and rank N. Therefore, if $\beta>1$ the asymptotic limit measure has an atom at zero of size at least $\beta-1$. On the other hand, if $L=N$ then with probability one the random matrix $\mathbf{V}^{*}\mathbf{V}$ has determinant equal to

$$\det(\mathbf{V}^{*}\mathbf{V}) = |\det(\mathbf{V})|^{2} = \frac{1}{N^{N}}\cdot\prod_{1\le p<q\le N}|e^{2\pi i\theta_p}-e^{2\pi i\theta_q}|^{2}. \tag{1.3}$$

This determinant is zero if and only if there exist distinct p and q such that $\theta_p=\theta_q$. This is an event of zero probability if the probability measure has a density. Therefore, the minimum singular value $\lambda_1(N)$ is positive with probability one and converges to zero as N increases. In this work, we show that with high probability $\lambda_1(N)\le N^{2}\exp(-C\sqrt{N})$. As a consequence of our argument we show that with high probability

$$\max\left\{\prod_{i=1}^{N}|z-z_i|^{2}\ :\ |z|=1\right\}\ge\exp(C\sqrt{N}), \tag{1.4}$$

where $z_k=e^{2\pi i\theta_k}$ and $\{\theta_1,\ldots,\theta_N\}$ are i.i.d in $[0,1]$. Moreover, we explicitly determine the constant C. We believe that this may prove to be of independent mathematical interest. Additionally, we show the absence of finite moments for the matrix $(\mathbf{V}^{*}\mathbf{V})^{-1}$.

Lastly, we present a generalized version of the previously discussed random Vandermonde matrices. More specifically, consider an increasing sequence of integers $\{k_p\}_{p=1}^{\infty}$ and let $\{\theta_1,\ldots,\theta_N\}$ be i.i.d. random variables uniformly distributed in the unit interval $[0,1]$. Let V be the $N\times N$ random matrix defined as

$$V(i,j):=\frac{1}{\sqrt{N}}z_j^{k_i} \tag{1.5}$$

where $z_j:=e^{2\pi i\theta_j}$. Note that if we consider the sequence $k_p=p-1$ then the matrix V is the usual random Vandermonde matrix defined in Equation (1.1). We study the limit eigenvalue distribution for the matrices $X:=VV^{*}$ and in particular their asymptotic moments. In this work we find a combinatorial formula for its moments and we show that for every sequence there exists a unique probability measure on $[0,\infty)$ with these moments. Finally, we show that for the sequence $k_p=2^{p}$ the limit eigenvalue distribution is the famous Marchenko–Pastur distribution.

The rest of the paper proceeds as follows. In Section 2, we present some preliminaries in random matrix theory, the Littlewood-Offord theory, we set up some notation and terminology and we review some known results for random Vandermonde matrices. In Section 3, we prove a formula for the trace log and log determinant of the random Vandemonde matrices. We also prove the absence of finite moments for the matrix $\mathbf{M}^{*}\mathbf{M}$ where $\mathbf{M}=\mathbf{V}^{-1}$. In Section 4, we show upper and lower bounds for the behavior of the maximum singular value of $\mathbf{V}^{(d)}$ in the general case. In Section 5, we study the behavior of the minimum singular value of $\mathbf{V}$. In Section 6, we present some numerical results that suggest the absence of an atom at zero for the limit eigenvalue for the square case. In the last Section, we analyze the moments and limit eigenvalue distributions of the generalized version of the random Vandermonde matrices as described before.

2. Preliminaries

2.1. **Random Matrix Theory Preliminaries.** Throughout the paper we will denote by $\mathbf{A}^*$ the complex conjugate transpose of the matrix $\mathbf{A}$ and the matrix $\mathbf{I}_N$ will represent the $N \times N$ identity matrix. We let Tr be the non–normalized trace for square matrices, $\mathrm{Tr}(\mathbf{A}) := \sum_{i=1}^{N} a_{ii}$, where a_{ii} are the diagonal elements of the matrix $\mathbf{A}$. We also let tr_N be the normalized trace, defined by $\mathrm{tr}_N(\mathbf{A}) = \frac{1}{N}\mathrm{Tr}(\mathbf{A})$. Let $\mathbf{A}_N = (a_{ij}(\omega))_{i,j=1}^{N}$ be a random matrix where the entries a_{ij} are random variables on some probability space. We say that the random matrices $\mathbf{A}_N$ converge to a random variable A in distribution if the moments of $\mathbf{A}_N$ converge to the moments of the random variable A. We will denote this by $\mathbf{A}_N \to A$.

One should notice that for a Hermitian $N \times N$ matrix $\mathbf{A} = \mathbf{A}^*$, the collection of moments corresponds to a probability measure $\mu_{\mathbf{A}}$ on the real line, determined by $\mathrm{tr}_N(\mathbf{A}^k) = \int_{\mathbb{R}} t^k \, d\mu_A(t)$. This measure is given by the eigenvalue distribution of $\mathbf{A}$, i.e. it puts mass $\frac{1}{N}$ on each of the eigenvalues of $\mathbf{A}$ (counted with multiplicity):

$$\mu_{\mathbf{A}} = \frac{1}{N}\sum_{i=1}^{N} \delta_{\lambda_i}, \tag{2.1}$$

where $\lambda_1, \ldots, \lambda_N$ are the eigenvalues of $\mathbf{A}$. In the same way, for a random matrix $\mathbf{A}$, $\mu_{\mathbf{A}}$ is given by the averaged eigenvalue distribution of $\mathbf{A}$. Thus, moments of random matrices with respect to the averaged trace contain exactly the type of information in which one is usually interested when dealing with random matrices.

Consider an $N \times L$ random Vandermonde matrix $\mathbf{V}$ with unit complex entries, as given in Equation (1.1). The variables θ_i will be called the phase distributions and let ν be their probability distribution. It was proved in [17] that if $d\nu = f(x)\,dx$ for $f(x)$ continuous in $[0,1]$ then the matrices $\mathbf{V}^*\mathbf{V}$ have finite asymptotic moments. In other words, the limit

$$m_r^{(\beta)} = \lim_{N\to\infty} \mathbb{E}\Big[\mathrm{tr}_L\Big((\mathbf{V}^*\mathbf{V})^r\Big)\Big] \tag{2.2}$$

exists for all $r \geq 0$. Moreover,

$$m_r^{(\beta)} = \sum_{\rho \in \mathcal{P}(r)} K_{\rho,\nu}\,\beta^{|\rho|-1} \tag{2.3}$$

where $K_{\rho,\nu}$ are positive numbers indexed by the partitions ρ. We call these numbers *Vandermonde expansion coefficients.*

The fact that all the moments exist is not enough to guarantee the existence of a limit probability measure having these moments. However, it was proved in [21] that the eigenvalues of $\mathbf{V}^*\mathbf{V}$ converge in distribution to a probability measure $\mu_{\beta,\nu}$ supported on $[0,\infty)$ where $\beta = \lim_{N\to\infty}\frac{L}{N}$.

More precisely,

$$m_r^{(\beta)} = \int_0^\infty t^r \, d\mu_{\beta,\nu}(t).$$

In [21], the class of functions for which the limit eigenvalue distribution exists was enlarged to include unbounded densities and lower bounds and upper bounds for the maximum eigenvalue were found. We suggest the interested reader to look at the articles [17] and [21] for more properties on the Vandermonde expansion coefficients as well as methods and formulas to compute them.

2.2. **Littlewood-Offord Theory Preliminaries.** Let $v_1, \ldots, v_n$ be n vectors in $\mathbb{R}^d$, which we normalise to all have length at least 1. For any given radius $\Delta > 0$, we consider the small ball probability

$$p(v_1, \ldots, v_n, \Delta) := \sup_B \mathbb{P}(\eta_1 v_1 + \ldots + \eta_n v_n \in B)$$

where $\eta_1, \ldots, \eta_n$ are i.i.d. Bernoulli signs (i.e. they take values $+1$ or -1 independently with a probability of $1/2$ of each), and B ranges over all (closed) balls of radius Δ. The Littlewood-Offord problem is to compute the quantity

$$p_d(n, \Delta) := \sup_{v_1, \ldots, v_n} p(v_1, \ldots, v_n, \Delta)$$

where $v_1, \ldots, v_n$ range over all vectors in $\mathbb{R}^d$ of length at least one. Informally, this number measures the extent to which a random walk of length n (with all steps of size at least one) can concentrate into a ball of radius Δ.

The one-dimensional case of this problem was answered by Erdös. First, one observes that one can normalise all the v_i to be at least $+1$ (as opposed to being at most -1). In the model case when $\Delta < 1$, he proved that

$$p_1(n, \Delta) = \binom{n}{\lfloor n/2 \rfloor} / 2^n = \frac{\sqrt{\frac{2}{\pi}} + o(1)}{\sqrt{n}}$$

when $0 \leq \Delta < 1$ (the bound is attained in the extreme case $v_1 = \ldots = v_n = 1$). A similar argument works for higher values of Δ, using Dilworth's Theorem instead of Sperner's Theorem, and gives the exact value

$$p_1(n, \Delta) = \sum_{j=1}^{s} \binom{n}{m_j} / 2^n = \frac{s\sqrt{\frac{2}{\pi}} + o(1)}{\sqrt{n}} \tag{2.4}$$

whenever $n \geq s$ and $s - 1 \leq \Delta < s$ for some natural number s, where $\binom{n}{m_1}, \ldots, \binom{n}{m_s}$ are the s largest binomial coefficients of $\binom{n}{1}, \ldots, \binom{n}{n}$. See the reference [20] for more details on the Littlewood–Offord Theory.

3. Trace Logarithm Formula and the Inverse of a Vandermonde Matrix

3.1. **Inverse of a Vandermonde Matrix.** Given a vector $\mathbf{x}$ in $\mathbb{C}^N$, we define $\sigma_r^m(\mathbf{x})$ to be the sum of all r-fold products of the components of $\mathbf{x}$ not involving the m-th coordinate. In other words,

$$\sigma_r^m = \sum_{\rho_r^m} \prod_{k \in \rho_r^m} x_k$$

where ρ_r^m is a subset of $\{x_1, x_2, \ldots, x_{m-1}, x_{m+1}, \ldots, x_N\}$, with cardinality r.

The following Theorem was proved in [11].

Theorem 1. *Let* $\mathbf{V}$ *be a square* $N \times N$ *matrix given by*

$$\mathbf{V} := \begin{pmatrix} 1 & 1 & \ldots & 1 \\ x_1 & x_2 & \ldots & x_N \\ \vdots & \vdots & \ddots & \vdots \\ x_1^{N-1} & x_2^{N-1} & \ldots & x_N^{N-1} \end{pmatrix} \tag{3.1}$$

with no 0 entries. Then its inverse $\mathbf{M} := \mathbf{V}^{-1}$ *is the matrix with entries*

$$\mathbf{M}(m,n) = \frac{(-1)^{N-n}\sigma_{N-n}^m(\mathbf{x})}{\prod_{j\neq m}(x_m - x_j)}$$

with $m, n \in \{1, 2, \ldots, N\}$.

Remark 1. *Let* $\nu_1 \leq \nu_2 \leq \ldots \leq \nu_N$ *be the eigenvalues of* $\mathbf{M}^*\mathbf{M}$ *and let* $\lambda_1 \leq \lambda_2 \leq \ldots \leq \lambda_N$ *be the corresponding eigenvalues of* $\mathbf{V}^*\mathbf{V}$*, which are the same as for* $\mathbf{V}\mathbf{V}^*$*. Note that*

$$\nu_k = \lambda_{N-(k-1)}^{-1}$$

and in particular $\nu_N = \lambda_1^{-1}$*. Therefore, to study* λ_1 *it is enough to understand the behavior of* ν_N*.*

Here we prove a Theorem about the trace log formula for the random Vandermonde matrices and a Theorem about the non-existence of the moments of $\mathbf{M}^*\mathbf{M}$, but first we need a Lemma.

Lemma 1. *Let* $\mathbf{M}$ *be an invertible* $N \times N$ *matrix with columns* $X_1, \ldots, X_N$ *and let* $R_1, \ldots, R_N$ *be the rows of* $\mathbf{M}^{-1}$*. Let* $\mathcal{V}_i$ *be the subspace generated by all the column vectors except* X_i*, i.e.,*

$$\mathcal{V}_i = \operatorname{span}\{X_1, X_2, \ldots, X_{i-1}, X_{i+1}, \ldots, X_N\}.$$

Then the distance between the vector X_i *and the subspace* $\mathcal{V}_i$ *is equal to*

$$\operatorname{dist}(X_i, \mathcal{V}_i) = \frac{1}{\|R_i\|}.$$

Moreover,

$$\sum_{i=1}^{N} \lambda_i(\mathbf{M}^*\mathbf{M})^{-1} = \sum_{i=1}^{N} \operatorname{dist}(X_i, \mathcal{V}_i)^{-2}.$$

Proof. The result follows from an identity involving the singular values of $\mathbf{M}$. By definition, the inner product $\langle R_k, X_\ell \rangle = \delta_{k,\ell}$ so that R_k is orthogonal to $\mathcal{V}_k$. Hence,

$$d(X_k, \mathcal{V}_k) = \frac{1}{||\mathbf{R}_k||}.$$

Let $\lambda_k(\mathbf{M}^*\mathbf{M})$ be the eigenvalues of $\mathbf{M}^*\mathbf{M}$. Then,

$$\operatorname{Tr}\left(\left(\mathbf{M}^{-1}\right)^* \mathbf{M}^{-1}\right) = \sum_{i=1}^{N} \lambda_i(\mathbf{M}^*\mathbf{M})^{-1}.$$

On the other hand,

$$\operatorname{Tr}\left(\left(\mathbf{M}^{-1}\right)^{*}\mathbf{M}^{-1}\right) = \sum_{1\leq k,\ell\leq N} |\left(\mathbf{M}^{-1}\right)_{k,\ell}|^2 = \sum_{k=1}^{N}||\mathbf{R}_k||^2.$$

□

Theorem 2. *Let* $\mathbf{V}$ *be a square random Vandermonde matrix of dimension* N *with i.i.d. phases distributed according to a measure* ν *with continuous density* $f(x)$ *over* $[0,1]$*. Then*

$$\mathbb{E}\Big[\operatorname{tr}_N \log(\mathbf{V}^*\mathbf{V})\Big] = (N-1)\,\mathbb{E}\big(\log|1-e^{2\pi i\theta}|\big) - \log(N). \tag{3.2}$$

Proof. The matrix $\mathbf{V}$ is an $N\times N$ random Vandermonde matrix as in Equation (1.1), with i.i.d. phases distributed according to a measure ν with continuous density $f(x)$. Let $0\leq\lambda_1\leq\lambda_2\leq\ldots\leq\lambda_N$ be the eigenvalues of $\mathbf{V}^*\mathbf{V}$. Note that $\lambda_1>0$ with probability one. It is clear that,

$$\log\det(\mathbf{V}^*\mathbf{V}) = \sum_{i=1}^{N}\log(\lambda_i). \tag{3.3}$$

On the other hand,

$$\det(\mathbf{V}^*\mathbf{V}) = \frac{1}{N^N}\cdot\prod_{1\leq p<q\leq N}|e^{2\pi i\theta_p}-e^{2\pi i\theta_q}|^2$$

hence

$$\log\det(\mathbf{V}^*\mathbf{V}) = \sum_{p<q}2\log(|e^{2\pi i\theta_p}-e^{2\pi i\theta_q}|) - N\log(N). \tag{3.4}$$

Since the phases are identically distributed it is easy to see that the expectation $\mathbb{E}\big[\log\det(\mathbf{V}^*\mathbf{V})\big]$ is equal to

$$\frac{N(N-1)}{2}\,\mathbb{E}\Big[2\log|e^{2\pi i\theta_p}-e^{2\pi i\theta_q}|\Big] - N\log(N) \tag{3.5}$$

which is

$$N(N-1)\,\mathbb{E}\Big[\log|1-e^{2\pi i\theta}|\Big] - N\log(N). \tag{3.6}$$

Since for every invertible Hermitian matrix $\mathbf{A}$ we have that $\operatorname{Tr}\log(\mathbf{A}) = \log\det(\mathbf{A})$, in particular we have that

$$\operatorname{tr}_N\log(\mathbf{V}^*\mathbf{V}) = \frac{1}{N}\log\det(\mathbf{V}^*\mathbf{V}). \tag{3.7}$$

Combining equations (3.5) and (3.7) we see that

$$\mathbb{E}\Big[\operatorname{tr}_N\log(\mathbf{V}^*\mathbf{V})\Big] = (N-1)\,\mathbb{E}\big[\log|1-e^{2\pi i\theta}|\big] - \log(N). \tag{3.8}$$

□

Theorem 3. *Let* $\mathbf{V}$ *be a square* $N\times N$ *random Vandermonde matrix. Then for every* $N\geq 2$ *the matrix* $\mathbf{V}^*\mathbf{V}$ *is invertible with probability one and*

$$\mathbb{E}\big(\operatorname{tr}_N\big((\mathbf{V}^*\mathbf{V})^{-p}\big)\big) = \infty$$

for every $p\geq 1$*.*

Proof. It is enough to prove the case $p = 1$ since the other cases follow from this one. From Lemma 1 we see that

$$\mathbb{E}\big(\mathrm{tr}_N\big((\mathbf{V}^*\mathbf{V})^{-1}\big)\big) = \frac{1}{N}\sum_{m,n=1}^{N}\mathbb{E}\big(|\mathbf{M}(m,n)|^2\big)$$

where $\mathbf{M} = \mathbf{V}^{-1}$. In particular,

$$\mathbb{E}\big(\mathrm{tr}_N\big((\mathbf{V}^*\mathbf{V})^{-1}\big)\big) \geq \frac{1}{N}\mathbb{E}\big(|\mathbf{M}(1,N)|^2\big).$$

Now using Theorem 1 we see that

$$\mathbb{E}\big(|\mathbf{M}(1,N)|^2\big) = \left[\frac{1}{2\pi}\int_0^{2\pi}\frac{d\theta}{|1-e^{i\theta}|^2}\right]^{N-1} = \infty.$$

□

4. Maximum Eigenvalue

Let $\mathbf{X}$ be the $L \times L$ matrix defined as $\mathbf{X} := {\mathbf{V}^{(2)}}^*\mathbf{V}^{(2)}$. Suppose that the phases (θ_k, ψ_k) are selected i.i.d. on $[0,1]^2$. We further suppose, as in [21], that $(\theta_k, \psi_k) - (\theta_1, \psi_1)$ given θ_1, ψ_1 has a conditional density (which exists for all (θ_1, ψ_1) if it exists for one) and denote this density by f ignoring its dependence on (θ_1, ψ_1) as it will only appear through $||f||_\infty$. It can be shown that $\mathbf{X}$ has the same eigenvalues as the matrix $\mathbf{A}$ whose entries are

$$A(k,m) := D_N\Big(2\pi(\theta_k - \theta_m)\Big) \cdot D_N\Big(2\pi(\psi_k - \psi_m)\Big) \tag{4.1}$$

where

$$D_N(x) := \frac{\sin(\frac{N}{2}x)}{N\sin(\frac{x}{2})}$$

is the Dirichlet kernel (see [21] for instance). Similarly, in the case $d \geq 3$ we obtain a product of d Dirichlet kernels. Subsequently, $\mathbf{A}$ will be used to construct upper and lower bounds for the maximum eigenvalue λ_L.

We now proceed to obtain asymptotic upper and lower bounds for d-fold Vandermonde matrices. We will first focus on the case $d = 2$ and retain the notation of Section 2. In what follows we will prove the following Theorem.

Theorem 4. *Let $\mathbf{V}^{(d)}$ be the $N^d \times L$ d-fold random Vandermonde matrix defined in (1.2). Let λ_L be the maximum eigenvalue of the matrix $(\mathbf{V}^{(d)})^*(\mathbf{V}^{(d)})$. Then, if $N, L \to \infty$ such that $\beta = \frac{L}{N^d} \in (0,\infty)$ there exist constants C_e such that for all $C > C_e$*

$$\mathbb{P}\Big(\lambda_L \geq C\log(N^d) + u\Big) \leq e^{-u}\frac{N^d}{N^{\delta(d-1)\log(N)}} \tag{4.2}$$

where $\delta = C - C_e$.

Proof. The line of argument follows that of [21]. We begin with the following upper bound for the Dirichlet function proved in [21],

$$\left|\frac{\sin(\frac{N}{2}|x|)}{N\sin(\frac{|x|}{2})}\right| \leq \sum_{k=1}^{N/2} \frac{1}{k}\cdot \mathbf{1}_{\left[\frac{2\pi(k-1)}{N},\frac{2\pi k}{N}\right)}(|x|). \tag{4.3}$$

To apply the bound, let $p_{a,b}$ be the probability with $a, b \in \mathbb{Z}$ such that

$$\theta_k - \theta_1 \in [(a-1)/N, a/N]$$

and

$$\psi_k - \psi_1 \in [(b-1)/N, b/N].$$

Define,

$$q_{a,b} := p_{a,b} + p_{-a,b} + p_{a,-b} + p_{-a,-b}$$

Then, it is easy to see that

$$q_{a,b} \leq \frac{4}{N^2}\|f\|_\infty = \frac{C_q}{N^2} \tag{4.4}$$

where the function f is the probability density over the square $[0,1]^2$. Next for the magnitude of a term in the first row, corresponding to θ_1, ψ_1 we find that

$$\mathbb{E}\big[\exp(Xt) \mid \theta_1, \psi_1\big] \leq \sum_{a=1}^{N/2}\sum_{b=1}^{N/2} q_{a,b} e^{\frac{t}{ab}} \leq 1 + (e-1)\sum_{a=1}^{N/2}\sum_{b=1}^{N/2} q_{a,b}\frac{t}{ab} \tag{4.5}$$

where X is defined as

$$X := \Big|D_N(2\pi(\theta_k - \theta_1))\cdot D_N(2\pi(\psi_k - \psi_1))\Big|$$

for $k \neq 1$ and the upper bound does not depend on k or (θ_1, ψ_1). If R is any row sum of the entries of the matrix $\mathbf{X}$ it follows that

$$\mathbb{E}\big[\exp(R)\big] \leq e\left[1 + C_q\frac{(e-1)}{N^2}H_{N/2}^2\right]^{L-1} \leq e^{\beta_N C_q(e-1)H_{N/2}^2} \tag{4.6}$$

by taking $t = 1$ and using the fact that $(1 + x/A)^A \leq \exp(x)$ and that $\beta_N \to \beta$ as $N \to \infty$ where $H_p := \sum_{k=1}^{p} 1/k$. Since

$$H_N = \log N + \gamma + \frac{1}{2N} + O(N^{-2})$$

it follows that

$$\mathbb{E}\big(\exp(R)\big) \leq e^{C_e(\log N)^2} = N^{C_e \log N} \tag{4.7}$$

for some suitable constant $C_e > 0$. Applying the union bound to the maximum row sum Y and then, Markov's inequality with $C \geq C_e + \delta$, we get

$$\mathbb{P}\Big(Y \geq C(\log N)^2 + u\Big) \leq e^{-u}\frac{N^2}{N^{C\log N}}\cdot N^{C_e \log N} = e^{-u}\frac{N^2}{N^{\delta \log N}}. \tag{4.8}$$

Since the maximum eigenvalue is upper bounded by the maximum row sum of magnitudes, then $Y \geq \lambda_L$. This concludes the proof for the case $d = 2$.

For the case $d > 2$ one obtains a d-fold product of Dirichlet functions so that the exponent of the Harmonic function H is d instead of 2 in (4.6) and also in (4.4). Constant terms are also suitably modified and with these changes carried through to (4.8) where 2 is again replaced with d, the result follows as before. ☐

The following Corollary is stated without proof.

Corollary 1. *There exists a positive constant B such that*

$$\mathbb{E}\left[\lambda_L\right] \leq B\log(N^d) + o(1).$$

4.1. **Lower Bound.** The purpose of this subsection is to present the following lower bound for the maximum eigenvalue λ_L, in which we suppose that phases are provided according to a joint continuous density f bounded away from 0.

Theorem 5. *Let λ_L be the maximum eigenvalue then if $N, L \to \infty$ such that $\lim_{N\to\infty} \frac{L}{N^d} = \beta \in (0,\infty)$ there exists a constant K such that*

$$\mathbb{P}\Big(\lambda_L \geq K\frac{\log N^d}{\log\log N^d}\Big) = 1 - o(1). \tag{4.9}$$

Proof. We rely on the equivalent matrix given in (4.1), which is an $L \times L$ matrix. For notation simplicity we specialize to the case $d = 2$ since the case $d \geq 3$ follows a similar argument. To construct our lower bound by analogy with the 1-dimensional case, we want to obtain large numbers of points (θ, ψ) which lie close together, that is points such that $|\theta_k - \theta_m|$ and $|\psi_k - \psi_m|$ are both small. By hypothesis the joint measure has a continuous density f bounded away from 0, throughout $[0,1]^2$. Therefore, it follows that

$$\eta := \min\left\{f(\theta,\psi)\,:\,(\theta,\psi)\in[0,1]^2\right\} > 0.$$

We randomly select L phase vectors in $[0,1]^2$ according to this measure. Let us divide the square $[0,1]^2$ in κN^2 equal squares. Each of of these squares will receive at least $\frac{L}{\kappa N^2}\eta$ points on average. This is an occupancy model and we are interested in the square which has the maximum number of points. The number of such points is at least

$$k(N^2) = \alpha\frac{\log N^2}{\log\log N^2},$$

with probability $1 - o(1)$, for all $\alpha \in (0,1)$ independently of the mean number of ball per urn (see for instance [15]). By dividing more finely and then taking N sufficiently large the entries of the matrix can be made arbitrarily close to 1 and so have maximum eigenvalue arbitrarily close to $k(N^2)$. Finally, using the interlacing Theorem as done in [21] on $\mathbf{A}$ the result is obtained as a lower bound on the maximum eigenvalue. ☐

5. Minimum Eigenvalue

In this section we focus on the behavior of the minimum eigenvalue λ_1 for the case $d = 1$. Consider the matrix $\mathbf{A}$ as in Equation (4.1) and all its 2×2 principal sub-minors. These matrices are symmetric and the minimum eigenvalue for the sub minor determined by phases θ_k and θ_ℓ will be denoted $\lambda_{k,\ell}$. In other words, $\lambda_{k,\ell}$ is the smaller root of the equation

$$(1 - \lambda_{k,\ell})^2 = D_N(2\pi(\theta_k - \theta_\ell))^2.$$

Taking square roots and again applying the interlacing Theorem we obtain,

$$\lambda_1(N) \leq \min_{k,\ell} \Big[1 - D_N(2\pi(\theta_k - \theta_\ell))\Big].$$

Let γ and C_N be defined as $\gamma := N^2 \min_{k,\ell} |\theta_k - \theta_\ell|$ and

$$C_N := \min_{k,\ell} \Big(1 - D_N(2\pi(\theta_k - \theta_\ell))\Big).$$

From a result of de Finetti (see [9] for a reference),

$$\mathbb{P}\Big(\min_{k,\ell} |\theta_k - \theta_\ell| > \delta\Big) = (1 - N\delta)_+^{N-1}$$

where $(x)_+ := \max\{x, 0\}$ and this operation is taken first. Substituting η/N^2 and taking the limit as $N \to \infty$ we obtain that

$$\lim_{N\to\infty} \mathbb{P}\Big(\min_{k,\ell} |\theta_k - \theta_\ell| > \frac{\eta}{N^2}\Big) = e^{-\eta}.$$

On taking the Taylor expansion of D_N to second order around the origin we obtain

$$\min_{k,\ell} \Big(1 - D_N(2\pi(\theta_k - \theta_\ell))\Big) = \frac{\pi^2\gamma^2}{6N^2} + o(N^{-2}).$$

Therefore, the following limit holds,

$$\lim_{N\to\infty} \mathbb{P}\Big(C_N \leq \frac{\gamma^2}{6N^2}\Big) = 1 - e^{-\gamma}.$$

Then, it follows that $\lambda_1(N) \leq O(N^{-2})$ as $N \to \infty$. As we will now show, the approach to zero is much more rapid. To obtain better estimates for $\lambda_1(N)$ as $N \to \infty$, we now consider the maximum eigenvalue of the inverse matrix.

Given an $N \times N$ matrix $\mathbf{M}$, we have the following matrix norms $||\mathbf{M}||_1 := \sup_j \left(\sum_{k=1}^N |M_{k,j}|\right)$ and $||\mathbf{M}||_2 := \sqrt{\lambda_N(\mathbf{M}^*\mathbf{M})}$. The following inequality is well known (see [10] for more details),

$$\frac{1}{\sqrt{N}} ||\mathbf{M}||_1 \leq ||\mathbf{M}||_2 \leq ||\mathbf{M}||_1.$$

We now prove the following Lemma which will be used later.

Lemma 2. *Let* $A(z) = a_0 z^n + a_1 z^{n-1} + \ldots + a_n$ *be a complex polynomial and let* $A^* := \max_{|z|=1} |A(z)|$ *be its maximum in the unit circle. Then*

$$\frac{|a_n| + \ldots + |a_0|}{n+1} \leq A^* \leq |a_n| + \ldots + |a_0|. \tag{5.1}$$

Proof. The second inequality follows immediately from the triangle inequality, so we concentrate on the first. It will be enough to show that

$$|a_k| \leq A^* \tag{5.2}$$

for all k. By applying Cauchy's integral Theorem and by using the fact that

$$\int_{|z|=1} z^{-i}\, dz = 0$$

for all $i \neq 1$, it is obtained that,

$$a_k = \frac{1}{2\pi i} \int_{|z|=1} \frac{A(z)}{z^{n-k+1}} dz \tag{5.3}$$

for all k. Therefore,

$$|a_k| \leq \frac{1}{2\pi} \int_0^{2\pi} |A(z(\theta))| d\theta \leq A^*$$

where the first inequality follows by upper bounding the integral, taken as a line integral with respect to θ around the unit circle, and the second inequality follows from the definition of A^*. By applying the inequality to each k we obtain the required lower bound. $\square$

In the following steps we find a bound on $\lambda_1(N)$ in terms of the maximum of a polynomial with roots on the unit circle. We begin with some definitions. Let $z_k = e^{2\pi i\theta_k}$ be the values determining the random Vandermonde matrix as in Equation (1.1). Let $P(z)$ be the polynomial defined as

$$P(z) := \prod_{k=1}^{N} (z - z_k) \,.$$

We further denote

$$P_p(z) := \frac{P(z)}{|z - z_p|}.$$

Let $\mathbf{M} = \mathbf{V}^{-1}$ be the inverse of the random Vandermonde matrix and let $M(p,q)$ denote its entries. Define

$$\beta_p := \sum_{q=1}^{N} |M(p,q)|. \tag{5.4}$$

By Theorem 1, we know that

$$\beta_p := \frac{\sqrt{N}}{\prod_{q\neq p} |z_p - z_q|} \Big(|\sigma_0^p| + \ldots + |\sigma_{N-1}^p| \Big). \tag{5.5}$$

In addition, let

$$T_p(z) := \frac{P(z)}{|P(z_p)|} = \prod_{q\neq p} \frac{(z - z_q)}{|z_p - z_q|}. \tag{5.6}$$

It follows from (5.5) and (5.1) that

$$\frac{\beta_p}{N} \leq \max_{|z|=1} \Big(\sqrt{N} \cdot |T_p(z)| \Big) \leq \beta_p$$

for all $p = 1, \ldots, N$. The following Lemma is a direct consequence of the Hadamard's inequality.

Lemma 3. *Let $z_1, \ldots, z_N$ be distinct points on the unit complex circle. Then there exists $p_0 \in \{1, \ldots, N\}$ such that,*

$$\prod_{q\neq p_0} |z_{p_0} - z_q| \leq N. \tag{5.7}$$

We are now in a position to prove the following Lemma, which provides upper and lower bounds on the minimum eigenvalue of a Vandermonde matrix, in terms of the polynomial T_p, defined in (5.6).

Lemma 4. *Let* $\lambda_1(N)$ *be the minimum eigenvalue of the random Vandermonde matrix as defined in (1.1) and* $T_p(z)$ *be as defined above. Then,*

$$\frac{1}{N^3 \max_p \left\{\max_{|z|=1} |T_p(z)|^2\right\}} \leq \lambda_1(N) \leq \frac{1}{\max_p \left\{\max_{|z|=1} |T_p(z)|^2\right\}}. \tag{5.8}$$

Moreover,

$$\lambda_1(N) \leq \frac{N^2}{\max_{|z|=1} \prod_{q\neq p_0} |z-z_q|^2}. \tag{5.9}$$

Proof. Since $||\mathbf{M}||_1 = \max\{\beta_p : p = 1, \ldots, N\}$, it follows that

$$\frac{||\mathbf{M}||_1}{N} \leq \sqrt{N} \cdot \max_p \left\{\max_{|z|=1} |T_p(z)|\right\} \leq ||\mathbf{M}||_1.$$

On the other hand,

$$\frac{1}{||\mathbf{M}||_1^2} \leq \lambda_1(N) \leq \frac{N}{||\mathbf{M}||_1^2}$$

from which we can deduce that

$$\frac{1}{N^3 \max_p \left\{\max_{|z|=1} |T_p(z)|^2\right\}} \leq \lambda_1(N) \leq \frac{1}{\max_p \left\{\max_{|z|=1} |T_p(z)|^2\right\}}. \tag{5.10}$$

Using Lemma 3, we know that there exists p_0 such that $\prod_{q\neq p_0} |z_{p_0} - z_q| \leq N$. We thus obtain that

$$\max_{|z|=1} |T_{p_0}(z)| \geq \max_{|z|=1} \left(\frac{1}{N} \prod_{q\neq p_0} |z - z_q| \right). \tag{5.11}$$

Therefore, using the fact that

$$\max_p \max_{|z|=1} |T_p(z)| \geq \max_{|z|=1} |T_{p_0}(z)|$$

and Lemma 4 we see that

$$\lambda_1(N) \leq \frac{N^2}{\max_{|z|=1} \prod_{q\neq p_0} |z-z_q|^2}. \tag{5.12}$$

□

5.1. **Stochastic Construction.** Before stating our upper bound for the minimum eigenvalue, we introduce the following definitions. First, we define a random sequence via a realization of the Brownian bridge W^o on $[0, 2\pi]$, which satisfies $W^o(0) = W^o(2\pi) = 0$. A φ shift of the Brownian bridge is defined by

$$W_\varphi^o(\theta) := \begin{cases} W^o(\varphi + \theta) - W^o(\varphi) & \text{if } 0 \leq \theta \leq 2\pi - \varphi, \\ W^o(\varphi + \theta - 2\pi) - W^o(\varphi) & \text{if } 2\pi - \varphi \leq \theta < 2\pi. \end{cases}$$

Further, define the infinite sequence $\Phi := \{\varphi_r\}_{r\geq 0}$ to be the sequence of dyadic phases on $[0, 2\pi]$. Given a realization of the Brownian bridge define the following function,

$$I_\varphi := \int_0^{2\pi} W_\varphi^o(\theta) \frac{\sin\theta}{1-\cos\theta} d\theta$$

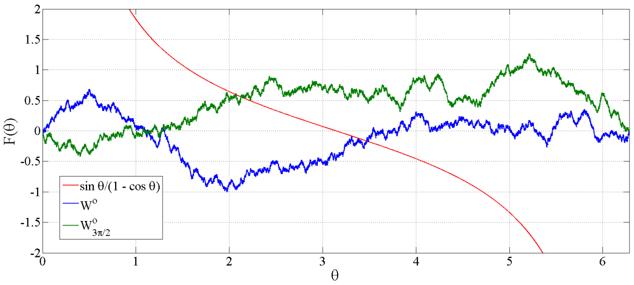

FIGURE 1. Realization of the Brownian Bridge and a Shifted Version.

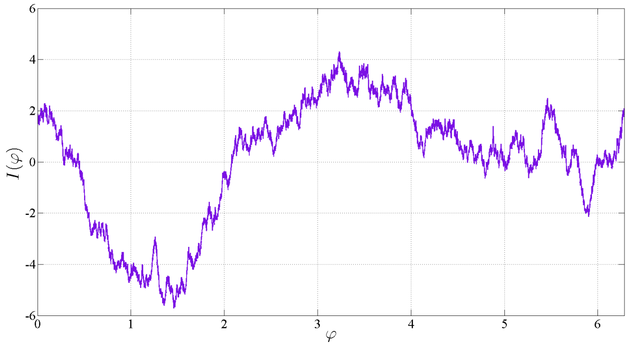

FIGURE 2. I_φ for the Brownian bridge previous realization.

for $\varphi \in [0, 2\pi]$. Note that it is not clear that the above integral is well defined, since it may not exist as the fraction $\frac{\sin\theta}{1-\cos\theta}$ behaves like θ^{-1} near 0 and near 2π. We will address this matter shortly. In Figure 1, we show a realization of the Brownian bridge and a shifted version with φ equal to $3\pi/2$. In Figure 2, we show I_φ for the same realization as before.

Using the sequence Φ and the same realization of W^o we construct the sequence of random variables $\mathbf{I} = \{I_r\}_{r\geq 0}$ as

$$I_r := I_{\varphi_r}.$$

It will be shown that I_φ is continuous on the interval $[0, 2\pi]$, and so there exists a value φ^* which determines the maximum value of I_φ, which we denote as I^*. Since Φ is dense on the unit circle, it follows that

$$I^* := \sup\{I_r : r \in \mathbb{N}\} \tag{5.13}$$

and its distribution is determined via the infinite sequence I_r. We now show that the above random function is well defined and that integrals are a.s. finite.

Lemma 5. *Given a realization of the Brownian bridge W^o, then a.s. the following integrals exist for all $\varphi \in [0, 2\pi)$*

$$|I_\varphi| = \left| \int_0^{2\pi} W^o_\varphi \frac{\sin\psi}{1-\cos\psi} d\psi \right| < \infty$$

In addition, the function $\varphi \mapsto I_\varphi$ is continuous.

Proof. When $\varphi = 0$ we write the above integral as I. The Levy global modulus of continuity tells us that for standard Brownian motion B on $[0, 2\pi)$ satisfies almost surely

$$\lim_{\delta \downarrow 0} \limsup_{0 \le t \le 2\pi - \delta} \frac{|B(t+\delta) - B(t)|}{w(\delta)} = 1$$

where $w(\delta) = \sqrt{2\delta \log \frac{1}{\delta}}$ (see [16] for a proof of this fact). Since W^o is by definition,

$$W^o(\psi) = B(\psi) - \frac{\psi}{2\pi} B(2\pi),$$

our argument will be the same no matter which value of φ is chosen because the Levy modulus applies to the entire sample path. We therefore set $\varphi = 0$. By definition of the Levy modulus, almost surely there exists $\delta_2 > 0$ such that

$$\frac{|B(t+\delta) - B(t)|}{w(\delta)} \le 2,$$

for all $0 < \delta \le \delta_2$. Therefore,

$$a(\delta) := |W^o(\psi + \delta) - W^o(\psi)| \le 2w(\delta) + \frac{B(2\pi)}{2\pi}\delta. \tag{5.14}$$

We may therefore split the integral as,

$$\begin{aligned} I &= \int_{\delta_2}^{2\pi - \delta_2} W^o(\psi) \frac{\sin\psi}{1 - \cos\psi} d\psi + \int_0^{\delta_2} W^o(\psi) \frac{\sin\psi}{1 - \cos\psi} d\psi \\ &+ \int_{2\pi - \delta_2}^{2\pi} W^o(\psi) \frac{\sin\psi}{1 - \cos\psi} d\psi. \end{aligned}$$

The first integral is finite being the integral of a continuous function over the interval $[\delta_2, 2\pi - \delta_2]$. We may further suppose that δ_2 has been chosen so that $|\psi \frac{\sin\psi}{1-\cos\psi}| \le 4$ for $0 < \psi < \delta_2$ with the corresponding inequality in a similar neighbourhood of 2π. By choice of δ_2 we obtain that

$$\Big| \int_0^{\delta_2} W^o(\psi) \frac{\sin\psi}{1 - \cos\psi} d\psi \Big| \le 8 \int_0^{\delta_2} \frac{a(\psi)}{\psi} d\psi < O(\delta_2^{1/3})$$

for sufficiently small δ_2. The same argument applies to the last integral. Since $w(\delta_2)$ gives a uniform bound the result holds for all $\varphi \in [0, 2\pi)$. Continuity in φ follows by a similar argument,

$$\begin{aligned} |I_\varphi - I_{\tilde{\varphi}}| &\leq \Big| \int_\delta^{2\pi-\delta} \left(W^o_\varphi - W^o_{\tilde{\varphi}}\right) \frac{\sin\psi}{1-\cos\psi} d\psi \Big| \\ &+ \int_0^\delta |W^o_\varphi(\psi)| \cdot \Big|\frac{\sin\psi}{1-\cos\psi}\Big| d\psi \\ &+ \int_{2\pi-\delta}^{2\pi} |W^o_\varphi(\psi)| \cdot \Big|\frac{\sin\psi}{1-\cos\psi}\Big| d\psi \\ &+ \int_0^\delta |W^o_{\tilde{\varphi}}(\psi)| \cdot \Big|\frac{\sin\psi}{1-\cos\psi}\Big| d\psi \\ &+ \int_{2\pi-\delta}^{2\pi} |W^o_{\tilde{\varphi}}(\psi)| \cdot \Big|\frac{\sin\psi}{1-\cos\psi}\Big| d\psi. \end{aligned} \tag{5.15}$$

Provided that $0 < \delta < \delta_2$, the tail integrals are all at most $O(\delta^{1/3})$ as before. We bound the first integral by two positive integrals, to obtain

$$\begin{aligned} \Big| \int_\delta^{2\pi-\delta} \left(W^o_\varphi - W^o_{\tilde{\varphi}}\right) & \frac{\sin\psi}{1-\cos\psi} d\psi \Big| \\ &\leq 2 \cdot \sup_{0\leq\psi\leq 2\pi} |W^o_\varphi(\psi) - W^o_{\tilde{\varphi}}(\psi)| \cdot \int_\delta^\pi \frac{\sin\psi}{(1-\cos\psi)} d\psi \\ &\leq 2 \cdot \sup |W^o_\varphi(\psi) - W^o_{\tilde{\varphi}}(\psi)| \cdot [(1-\cos\psi)]_\delta^\pi \\ &\leq 12a(\delta)\left(\log 2 - \log(1-\cos\delta)\right) \end{aligned}$$

provided $|\varphi - \tilde{\varphi}| < \delta$. Finally, $12a(\delta)\left(\log 2 - \log(1-\cos\delta)\right) \to 0$ as $\delta \to 0$, which implies continuity. □

It therefore follows that I^* is well defined. Let $T_N(\varphi)$ be defined as

$$T_N(\varphi) := \frac{1}{\sqrt{N}} \log|P(e^{i\varphi})|^2 = \frac{1}{\sqrt{N}} \sum_{q=1}^N \log\left[2(1-\cos(\varphi-\theta_q))\right] \tag{5.16}$$

where $P(z)$ is the random polynomial in the unit circle with roots $\{e^{i\theta_q}\}_{q=1}^N$ as before. Furthermore, define the infinite sequence of random variables $T_N(\varphi_r)$ by evaluating the previous expression at the phases of Φ. Note that T_N cannot be defined as a random function in either $C[0, 2\pi]$ or in $D[0, 2\pi]$ as its discontinuities are not of the first kind. We remark that since there are only countably many φ_r and the phases θ_q are i.i.d. and uniformly distributed then no φ_r coincides with any θ_q almost surely so that the sum exists. We further observe that since,

$$\int_0^{2\pi} \log\left[2(1-\cos(\psi))\right] d\psi = 0$$

and

$$\int_0^{2\pi} \log^2\left[2(1-\cos(\psi))\right] d\psi < \infty.$$

Note that the sequence $T_N(\varphi_r)$ satisfies the central limit Theorem as a function of N for every $r \in \mathbb{Z}_+$. We consider the sequence $\mathbf{T}_N := \{T_N(\varphi_r)\}_{r\geq 0}$ in the sequence space $\mathbb{R}^\infty$ with metric

$$\rho_0(\mathbf{x}, \mathbf{y}) = \sum_{\ell=0}^{\infty} \frac{|x_\ell - y_\ell|}{1 + |x_\ell - y_\ell|} 2^{-\ell}$$

and using the ordering stated earlier. It is well known that this forms a Polish space ([4]). We now derive one more Lemma for use later on.

Lemma 6. *Let Y be a function in $D[0, 2\pi]$. Then Y is Lebesgue measurable, and its integral exists,*

$$\int_0^{2\pi} Y(s)ds < \infty. \tag{5.17}$$

Furthermore, let Y_n be a sequence of functions in $D[0, 2\pi]$ such that $Y_n \to Y$ in D (i.e. with respect to the Skorohod topology) then

$$\int_0^{2\pi} Y_n(s)ds \to \int_0^{2\pi} Y(s)ds. \tag{5.18}$$

Proof. The existence of the integral follows from Lemma 1, page 110 of [4] and the subsequent discussion which shows that functions in D on a closed bounded interval are both Lebesgue measurable and bounded. The former follows from the fact that they may be uniformly approximated by simple functions, a direct consequence of Lemma 1 and the latter also.

Convergence follows from the Lebesgue dominated convergence theorem. This holds since the sequence Y_n is uniformly bounded, by a constant so the sequence is dominated. Second Y is continuous a.e. with pointwise convergence holding at points of continuity, as a consequence of convergence in D see [4]. □

We now proceed to prove the following Theorem.

Theorem 6. *With the topology induced by the previous metric in $\mathbb{R}^\infty$ we have that the sequence $\mathbf{T}_N$ converges in distribution to the sequence $\mathbf{I}$*

$$\mathbf{T}_N \Rightarrow \mathbf{I} \tag{5.19}$$

as $N \to \infty$.

Proof. In order to do so we will Theorem 4.2 of [4]. Suppose that there is a metric space $\mathcal{S}$ with metric ρ_0 and sequences $\mathbf{T}_{N,\varepsilon}$, $\mathbf{I}_\varepsilon$ and $\mathbf{T}_N$ all lying in $\mathcal{S}$ such that the following conditions hold,

$$\begin{aligned} \mathbf{T}_{N,\varepsilon} &\Rightarrow \mathbf{I}_\varepsilon \\ \mathbf{I}_\varepsilon &\Rightarrow \mathbf{I} \end{aligned} \tag{5.20}$$

together with the further condition that given arbitrary $\eta > 0$,

$$\lim_{\varepsilon\to 0} \limsup_{N\to\infty} \mathbb{P}\Big(\rho_0(\mathbf{T}_{N,\varepsilon}, \mathbf{T}_N) \geq \eta\Big) = 0. \tag{5.21}$$

Then it holds that $\mathbf{T}_N \Rightarrow \mathbf{I}$. First, we define $\mathbf{I}_\varepsilon$ using a realisation of the Brownian Bridge as follows,

$$I_{r,\varepsilon} := \big[W^o_{\varphi_r}(\psi) \log 2(1 - \cos\psi)\big]_{\varepsilon}^{2\pi-\varepsilon} - \int_{\varepsilon}^{2\pi-\varepsilon} W^o_{\varphi_r} \frac{\sin\psi}{1 - \cos\psi} d\psi.$$

The definition of the other sequence is more involved and so we defer it for a moment. We have shown that the limit integrals exist a.s. and so we only need to show that the first term converge to 0. Since $\log\big[2\,(1-\cos\psi)\,\big]=O(\log\varepsilon)$ when ε is small and in a neighbourhood of 0 and 2π we may invoke the Levy modulus of continuity, wrapped around at 2π to obtain that this term is

$$O(\log\varepsilon\times a(\varepsilon))\to 0.$$

Hence coordinate convergence of the integrals holds so that

$$\Big|I_{r,\varepsilon}+\int_{\varepsilon}^{2\pi-\varepsilon}W^{o}_{\varphi_r}\frac{\sin\psi}{1-\cos\psi}d\psi\Big|\Rightarrow 0$$

and it follows that $\mathbf{I}_{\varepsilon}\Rightarrow\mathbf{I}$ as $\varepsilon\downarrow 0$, since the sign of the integral is immaterial. We have thus demonstrated the second condition of (5.21). Finally, we proceed by rewriting $T_N(\varphi_r)$ in terms of the empirical distribution function $F_N:[0,2\pi]\to[0,1]$ determined by

$$F_N(\psi):=\frac{\#\left\{\theta_q: 0\le\theta_q\le\psi\right\}}{N}.$$

It is a straight forward observation to see that

$$\begin{aligned}T_N(\varphi_r) &= \sqrt{N}\int_0^{2\pi}\log\big[2(1-\cos(\varphi_r-\psi))\big]dF_N(\psi)\\ &= \sqrt{N}\int_0^{2\pi}\log\big[2(1-\cos\tilde{\psi})\big]dF_{N,\varphi_r}(\tilde{\psi})\end{aligned}$$

where the change of variables, $\tilde{\psi}=\psi-\varphi$ has been made. For $\psi\in[0,2\pi)$ we define $F_{N,\varphi}(\psi)$ as the "cycled" empirical distribution function of F_N by

$$F_{N,\varphi}(\psi):=\begin{cases}\frac{\#\{\varphi\le\theta_q<\varphi+\psi\}}{N} & \text{if } \varphi\le\psi<2\pi-\varphi,\\ F_{N,\varphi}(2\pi)+\frac{\#\{0\le\theta_q\le\psi-2\pi+\varphi\}}{N} & \text{if } 2\pi-\varphi\le\psi<2\pi.\end{cases}$$

To define the sequence $T_{N,\varepsilon}(\varphi_r)$ we split the integral into two parts as in $\int_{\varepsilon}^{2\pi-\varepsilon}$ and $\int_0^{\varepsilon}+\int_{2\pi-\varepsilon}^{2\pi}$ and then use integration by parts on the first part, which yields the expression,

$$\begin{aligned}T_{N,\varepsilon}(\varphi_r) &:= \sqrt{N}\times\left(\left[\left(F_{N,\varphi_r}(\psi)-\frac{\psi}{2\pi}\right)\log 2(1-\cos\psi)\right]_{\varepsilon}^{2\pi-\varepsilon}\right) \qquad (5.22)\\ &- \sqrt{N}\int_{\varepsilon}^{2\pi-\varepsilon}\left(F_{N,\varphi_r}(\psi)-\frac{\psi}{2\pi}\right)\frac{\sin\psi}{(1-\cos\psi)}d\psi.\end{aligned}$$

For later use we make the definition,

$$W_{N,\varphi}:=\sqrt{N}\left(F_{N,\varphi}(\psi)-\frac{\psi}{2\pi}\right).$$

This is not quite equal to the original sum, since

$$\int_0^{2\pi}\log\big[2\,(1-\cos\psi)\,\big]d\psi=0$$

so that the ψ terms do not give 0 but rather cancel with μ_ε to be defined in a moment. The remainder we express it as a sum, noting that we must include the mean, which is by symmetry,

$$\mu_\varepsilon := \frac{2}{2\pi}\int_0^\varepsilon \log\left[2\left(1-\cos\psi\right)\right]d\psi = \frac{2}{\pi}\left(\varepsilon\log\varepsilon - \varepsilon + o(\varepsilon)\right). \tag{5.23}$$

Define $S_\varepsilon(\varphi) := \{\theta_q : \theta_q \in [\varphi-\varepsilon, \varphi+\varepsilon]\}$ and hence the sum may be written as

$$Z_{N,\varepsilon}(\varphi_r) := \frac{1}{\sqrt{N}}\sum_{\theta_q\in S_\varepsilon(\varphi_r)} \log\left[2(1-\cos(\varphi_r-\theta_q))\right] - \sqrt{N}\mu_\varepsilon. \tag{5.24}$$

Denote the corresponding sequence as $\mathbf{Z}_{N,\varepsilon}$. Taking expectations we thus find that

$$\mathbb{E}\left[Z_{N,\varepsilon}(\varphi_r)\right] = \frac{N}{\sqrt{N}}\int_{-\varepsilon}^{\varepsilon}\log\left[2(1-\cos(\psi))\right]d\psi - \sqrt{N}\mu_\varepsilon = 0$$

is a sequence of random variables with 0 mean. We finally write,

$$\mathbf{T}_N = \mathbf{T}_{N,\varepsilon} + \mathbf{Z}_{N,\varepsilon}. \tag{5.25}$$

We now proceed to demonstrate the first condition of (5.21), namely that, $\mathbf{T}_{N,\varepsilon} \Rightarrow \mathbf{I}_\varepsilon$. Since $T_{N,\varepsilon}(\varphi_r)$ is a functional of an empirical distribution and therefore of a process lying in $D[0,2\pi]$. Define the random sequence J_ε defined for $f\in D[0,2\pi], f(0)=f(2\pi)=0$ with the component term,

$$J_{\varepsilon,r}(f) = \int_\varepsilon^{2\pi-\varepsilon} f_{\varphi_r}(\psi)\frac{\sin\psi}{(1-\cos\psi)}d\psi - \Big[f_{\varphi_r}(\psi)\log\left[2(1-\cos\psi)\right]\Big]_\varepsilon^{2\pi-\varepsilon}. \tag{5.26}$$

It is well known that,

$$W_{N,0} \Rightarrow W^o$$

in D, which implies that

$$W_{N,\varphi_r} \Rightarrow W^o_{\varphi_r}$$

as $N\to\infty$ for all r. The result will follow on showing that J_ε defines a measurable mapping $J_\varepsilon : D[0,2\pi]\to\mathbb{R}^\infty$ in $D[0,2\pi]$. Since

$$J_{\varepsilon,r}(W_N) = T_{N,\varepsilon}(\varphi_r),$$

we may therefore apply Theorem 5.1, Corollary 1 of [4] which states that if $W_N \Rightarrow W^o$ then $J_\varepsilon(W_N) \Rightarrow J_\varepsilon(W^o)$, (and hence $\mathbf{T}_{N,\varepsilon}\Rightarrow \mathbf{I}_\varepsilon$) provided that we verify

$$\mathbb{P}\Big(W^o \in D_{J_\varepsilon}\Big) = 0. \tag{5.27}$$

To deal with measurability question we first observed that the coordinate maps are measurable and since $\sin\psi/(1-\cos\psi)$ is continuous in $[\varepsilon, 2\pi-\varepsilon]$, it follows by Lemma 6 that $J_{\varepsilon,r}$ is measurable for each r and hence so is the sequence mapping J_ε. Again by Lemma 6 the sequence of integrals convergence with respect to ρ_0. This leaves only the final term. However since the limit W^o is almost surely continuous it follows almost surely that

$$\begin{aligned} f_{\varphi_r}(\varepsilon) &\to W^o_{\varphi_r}(\varepsilon) \\ f_{\varphi_r}(2\pi-\varepsilon) &\to W^o_{\varphi_r}(2\pi-\varepsilon) \end{aligned}$$

for each r if $f\to W^o$ in $D[0,2\pi]$. Thus the corresponding sequence converges with respect to ρ_0 also and so (5.27) holds. The proof of the first condition is concluded.

It remains to demonstrate (5.21). Here we will use the union bound and Chebyshev's inequality. This is because the various $Z_{N,\varepsilon}(\varphi_r)$ in the sequences are dependent, as they are determined via the same θ_q. Nevertheless they are of course themselves the sum of i.i.d. random variables. In determining the variance, we may work with $\varphi_r = 0$ without loss of generality. The variance of one of the i.i.d. summands in (5.24) is determined as

$$\sigma_\varepsilon^2 := \frac{2}{2\pi}\int_0^\varepsilon \log^2\big[2(1-\cos(\psi))\big]\,d\psi - \mu_\varepsilon^2 < \infty. \tag{5.28}$$

Since for small $\varepsilon > 0$ we have $\log\big[2(1-\cos(\psi))\big] = O(2\log\psi) + o(\psi)$ the integral is $\sigma_\varepsilon = O(\varepsilon\log^2\varepsilon)$ as the integral of $\log^2 x$ is $x\log^2 x - 2x\log x + 2x$. It follows that $\sigma_\varepsilon^2 \to 0$ as $\varepsilon \to 0$, which is the variance of the entire sum by independence and as it has been scaled.

Now fix $\eta > 0$. By definition of ρ_0 and from (5.25) we obtain that,

$$\rho_0(\mathbf{T}_{N,\varepsilon}, \mathbf{T}_N) = \sum_{r=0}^{\infty} \frac{|Z_{N,\varepsilon}(\varphi_r)|}{1 + |Z_{N,\varepsilon}(\varphi_r)|} 2^{-r}.$$

Let R_η be such that $\sum_{r=R_\eta+1}^{\infty} 2^{-r} < \eta/2$. Now we apply the union bound to the remaining $R_\eta + 1$ summands to obtain that

$$\begin{aligned}
\mathbb{P}\Big(\sum_{r=0}^{R_\eta} \frac{|Z_{N,\varepsilon}(\varphi_r)|}{1+|Z_{N,\varepsilon}(\varphi_r)|}2^{-r} \geq \eta/2\Big) &\leq \sum_{r=0}^{R_\eta} \mathbb{P}\Big(|Z_{N,\varepsilon}(\varphi_r)|2^{-r} \geq \frac{\eta}{2\,(R_\eta+1)}\Big) \\
&\leq \sum_{r=0}^{R_\eta} \sigma_\varepsilon^2 \frac{4\,(R_\eta+1)^2}{\eta^2 2^{2r}} \\
&\leq \sigma_\varepsilon^2 \frac{16\,(R_\eta+1)^2}{3\eta^2}.
\end{aligned} \tag{5.29}$$

Hence,

$$\limsup_N \mathbb{P}\Big(\rho_0(\mathbf{T}_{N,\varepsilon}, \mathbf{T}_N) > \eta\Big) \leq \frac{16(R_\eta+1)^2\sigma_\varepsilon^2}{3\eta^2},$$

and the RHS goes to 0 as ε to 0, for each $\eta > 0$. Hence we obtain (5.21) as required. We have therefore verified all conditions and Theorem 6 is proved. □

We are now in a position to state our main result for an upper bound on the minimum eigenvalue of a random Vandermonde matrix.

Theorem 7. *Let $\lambda_1(N)$ be the minimum eigenvalue of the square $N \times N$ matrix $\mathbf{V}$ defined in (1.1). We further assume that the phases $\theta_1, \ldots, \theta_N$ are i.i.d. and drawn accordingly to the uniform distribution. Then*

$$\lambda_1(N) \leq 2N^2 \exp\big(-\sqrt{N}T_N^*/2\big) \tag{5.30}$$

where $T_N^* := \limsup_r T_N(\varphi_r)$. Moreover, given $a > 0$,

$$\liminf_N \mathbb{P}\Big(\lambda_1(N) \leq 2N^2\exp\big(-\sqrt{N}a/2\big)\Big) \geq \mathbb{P}\Big(I^* > a\Big). \tag{5.31}$$

Proof. Using the definition of $T_N(\varphi_r)$ in (5.16) and the upper bound on the minimum eigenvalues as given in (5.9) as well as the inequality

$$\max_{|z|=1} \prod_{q \neq p_0} |z - z_q| \geq \frac{1}{2} \max_{|z|=1} \prod_{q} |z - z_q|$$

we obtain that,

$$\lambda_1(N) \leq 2N^2 \exp\big(-\sqrt{N} T_N(\varphi_r)/2 \big).$$

Since this equation holds over all $r \in \mathbb{Z}_+$ it follows that,

$$\lambda_1(N) \leq 2N^2 \exp\big(-\sqrt{N} \limsup_r T_N(\varphi_r)/2 \big). \tag{5.32}$$

Since this holds for all $N \in \mathbb{N}$ we obtain (5.30), which is the first part of the Theorem. Now define the random variable,

$$L_N := -\frac{2}{\sqrt{N}} \log \frac{\lambda_1(N)}{N^2}$$

and further for any given R define $T_{N,R} := \max_{r \leq R} \{T_N(\varphi_r)\}$, and similarly define I_R^*. Then for any fixed R and $a > 0$

$$\mathbb{P}\Big(L_N > a \Big) \geq \mathbb{P}\Big(T_{N,R} > a \Big)$$

by definition of $T_{N,R}$. By weak convergence, since the set is open, and by Theorem 2.1 of [4] we obtain,

$$\liminf_N \mathbb{P}\Big(L_N > a \Big) \geq \liminf_N \mathbb{P}\Big(T_{N,R} > a \Big) \geq \mathbb{P}\Big(I_R^* > a \Big)$$

as a consequence of Theorem 6. Finally by almost sure continuity it holds that $I_R^* \uparrow I^*$ almost surely, and so by the monotone convergence theorem we see that $\mathbb{P}\Big(I^* > a \Big) = \lim_R \mathbb{P}\Big(I_R^* > a \Big)$ which implies our result. ☐

5.2. **Analytical and Combinatorial Construction.** In this Section we present an analytical and elementary argument for the upper bound of the minimum eigenvalue. Let $z_1, z_2, \ldots, z_N$ be complex numbers in the unit circle and let $P(z) = \prod_{i=1}^{N} (z - z_i)$ be the polynomial with these roots. We want to estimate $\max_{|z|=1} |P(z)|$ when the roots $\{z_i\}_{i=1}^N$ are uniformly distributed i.i.d. random variable in the unit circle.

Lemma 7. *Given* $P(z)$ *as before there exists* $|w| = 1$ *such that* $|P(w)P(-w)| = 1$.

Proof. Consider the function $\Psi(z) = \log|P(z)| + \log|P(-z)|$. This function is continuous except at the values $\{z_1, -z_1, \ldots, z_N, -z_N\}$ where it has a vertical asymptote going to $-\infty$. Therefore, we can consider this function as a continuous function from the unit circle to $[-\infty, \infty)$ with the usual topology. On the other hand, it is clear that $\int_{|z|=1} \Psi(z) = 0$. Therefore, there exist w such that $\Psi(w) = 0$ and hence $|P(w)||P(-w)| = 1$. ☐

Consider the following construction. We first randomly choose the points $\{z_i\}_{i=1}^N$ and we consider the set of pairs $\mathcal{P} := \{(z_1, -z_1), \ldots, (z_N, -z_N)\}$. Note that by changing z_i by $-z_i$ does not affect the value of the point w in the previous Lemma. Hence the set $\mathcal{P}$ determines the point w. Now we fix this point and consider $\alpha_i := |w - z_i|$ and $\beta_i := |w + z_i|$. Since $|P(w)P(-w)| = 1$ we see that $\prod_{i=1}^{N} \alpha_i\beta_i = 1$. It is also clear that $\beta_i = \sqrt{4 - \alpha_i^2}$.

Let y be the random variable defined as $y : \{1, -1\}^N \to \mathbb{R}$

$$y(v_1, v_2, \ldots, v_N) = \sum_{i=1}^{N} v_i \log(\alpha_i/\beta_i)$$

taking signs i.i.d. at random with probability 1/2. It is not difficult to see that $\mathbb{E}(y) = 0$ where the average is taken over the set $\{1, -1\}^N$. Note that $y(v_1, \ldots, v_N)$ is equal to

$$\begin{aligned} y(v_1, \ldots, v_N) &= \sum_{i=1}^{N} v_i(\log(\alpha_i) - \log(\beta_i)) \\ &= \log |P_{(v_1,\ldots,v_N)}(w)| - \log |P_{(v_1,\ldots,v_N)}(-w)| \end{aligned}$$

where $P_{(v_1,\ldots,v_N)}(z)$ is the polynomial with roots $v_i z_i$

$$P_{(v_1,\ldots,v_N)}(z) = \prod_{i=1}^{N} (z - v_i z_i) \tag{5.33}$$

and w is as in Lemma 7. Since $|P_{(v_1,\ldots,v_N)}(-w)| = |P_{(v_1,\ldots,v_N)}(w)|^{-1}$ we see that

$$y(v_1, \ldots, v_N) = \log |P_{(v_1,\ldots,v_N)}(w)|^2. \tag{5.34}$$

Theorem 8. *Let* $\gamma := \log\left(\frac{\cos(\pi/8)}{\sin(\pi/8)}\right)$. *For every* $\epsilon > 0$ *the following holds*

$$\mathbb{P}\Big(|y(v_1, \ldots, v_N)| \geq \gamma\sqrt{\pi}\epsilon\sqrt{N}/2\Big) \geq 1 - \epsilon.$$

Proof. By changing z_i to $-z_i$, if necessary, we can assume without loss of generality that $\alpha_i \geq \beta_i$. The point w is equal to $w = e^{i\theta}$ for some phase θ in $[0, 2\pi)$. Let $\mathcal{A}$ be the set

$$\mathcal{A} := \Big\{e^{i\phi} \ : \ \phi \in [\theta + \pi/4, \theta + 3\pi/4] \cup [\theta - 3\pi/4, \theta - \pi/4]\Big\}.$$

The total length of the set $\mathcal{A}$ is π and hence the probability of random point z_i to belong to $\mathcal{A}$ is equal to 1/2. On the other hand, it is easy to see that if z_i belongs to $\mathcal{A}^c$ and since by assumption $\alpha_i \geq \beta_i$ we see that

$$\log(\alpha_i/\beta_i) \geq \log\left(\frac{\cos(\pi/8)}{\sin(\pi/8)}\right) =: \gamma \approx 0.8814.$$

Let us order the values of $\log(\alpha_i/\beta_i)$ in increasing order. Up to a re-numeration we see that

$$0 \leq \ldots \leq \log(\alpha_m/\beta_m) \leq \gamma \leq \log(\alpha_{m+1}/\beta_{m+1}) \leq \ldots \leq \log(\alpha_N/\beta_N).$$

The value of m is a random variable that converges almost surely to $N/2$ as $N \to \infty$. Without loss of generality and for notation simplicity we will assume that $m = N/2$, however, and as the argument shows this is not strictly necessary. Let $\epsilon > 0$ and let us consider the value $\sup_I \mathbb{P}(y(v_1, \ldots, v_N) \in I)$ where I ranges over all the closed intervals of length $\gamma\sqrt{\pi}\epsilon\sqrt{N}$ in the real line. By applying the Littlewood–Offord Theorem discussed in the preliminaries section we see that

$$\sup_I \Big\{\mathbb{P}\Big(y(v) \in I \mid \text{conditioning on } v_i \text{ for } i \leq \lfloor N/2 \rfloor\Big)\Big\} = \epsilon + o(N^{-1/2}) \tag{5.35}$$

for N sufficiently large. On the other hand,

$$\sup_I \Big\{ \mathbb{P}\big(y(v_1,\dots,v_N) \in I \big) \Big\}$$

is equal to

$$\frac{1}{2^{N/2}} \sum_{(v_1,\dots,v_{\lfloor N/2 \rfloor})} \sup_I \Big\{ \mathbb{P}\Big(y(v) \in I \mid \text{cond. on the first } v_i \Big) \Big\} \leq \epsilon$$

where the last inequality is coming from Equation (5.35). In particular taking I to be the interval $I = [-\gamma\sqrt{\pi}\epsilon\sqrt{N}/2, \gamma\sqrt{\pi}\epsilon\sqrt{N}/2]$ we conclude that

$$\mathbb{P}\Big(|y(v_1,\dots,v_N)| \geq \gamma\sqrt{\pi}\epsilon\sqrt{N}/2 \Big) \geq 1-\epsilon.$$

□

Theorem 9. *Given $\epsilon > 0$ we have that*

$$\mathbb{P}\Big(\max_{|z|=1} |P(z)|^2 \geq \exp(\gamma\sqrt{\pi}\epsilon\sqrt{N}/2) \Big) \geq 1-\epsilon \tag{5.36}$$

for N sufficiently large.

Proof. As we mentioned before we start by randomly generating n pairs of diametrically opposite points $(z_i, -z_i)$, and then find w as in Lemma 7. Finally fix the z_i by the N independent coin flips $(v_1,\dots,v_N)$. Now we condition on this event. We observed before that $|P_{(v_1,\dots,v_N)}(-w)| = |P_{(v_1,\dots,v_N)}(w)|^{-1}$. Therefore,

$$\log |P_{(v_1,\dots,v_N)}(w)| = -\log |P_{(v_1,\dots,v_N)}(-w)|.$$

Let $a(w)$ be

$$\begin{aligned} a(w) &= \log |P_{(v_1,\dots,v_N)}(w)| - \log |P_{(v_1,\dots,v_N)}(-w)| \\ &= \log |P_{(v_1,\dots,v_N)}(w)|^2. \end{aligned}$$

Then by the previous Theorem and Equation (5.34) we see that

$$\mathbb{P}\Big(|a(w)| \geq \gamma\sqrt{\pi}\epsilon\sqrt{N}/2 \Big) \geq 1-\epsilon.$$

Since $a(-w) = -a(w)$ we clearly see that

$$\mathbb{P}\big(\max\big(a(w), a(-w)\big) \geq \sqrt{\pi}\epsilon\sqrt{N}/2 \big) \geq 1-\epsilon.$$

Therefore,

$$\mathbb{P}\Big(\max_{|z|=1} \max\{\log |P_{(v_1,\dots,v_N)}(z)|^2, \log |P_{(v_1,\dots,v_N)}(-z)|^2\} \geq \sqrt{\pi}\epsilon\sqrt{N}/2 \Big) \geq 1-\epsilon. \tag{5.37}$$

Now removing the conditioning on the pairs $\{z_1, -z_1, \dots, z_N, -z_N\}$ we see that,

$$\mathbb{P}\left(\max_{|z|=1} |P(z)|^2 \geq \exp\left(\sqrt{\pi}\epsilon\sqrt{N}/2\right) \right) \geq 1-\epsilon \tag{5.38}$$

for N sufficiently large. □

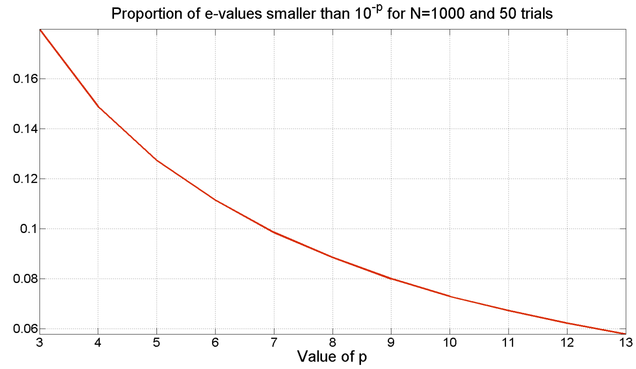

FIGURE 3. Graph of the average proportion of eigenvalues smaller than 10^{-p} as a function of p for $N = 1000$.

Since we already saw in Lemma 4 that

$$\lambda_1 \leq \frac{N^2}{\max_{|z|=1} |P(z)|^2}$$

the following Theorem follows immediately.

Theorem 10. *Given $\epsilon > 0$ we have that*

$$\mathbb{P}\Big(\lambda_1 \leq N^2 \exp(-\sqrt{\gamma\pi}\epsilon\sqrt{N}/2)\Big) \geq 1 - \epsilon. \tag{5.39}$$

6. NUMERICAL RESULTS

6.1. **Atom at 0.** In this subsection we present some numerical results for the behavior near the origin of the limit probability distribution of $\mathbf{V}^*\mathbf{V}$. Let $\mathbf{V}$ be a square $N \times N$ random Vandermonde matrix with phases $\theta_1, \theta_2, \ldots, \theta_N$ which are i.i.d. uniformly distributed on $[0, 1]$. We know that the empirical eigenvalue distribution of $\mathbf{V}^*\mathbf{V}$ converges as $N \to \infty$ to a probability measure μ. One question that we would like to address is: does the measure μ have an atom at zero?

Let $\{\lambda_i\}_{i=1}^N$ be the eigenvalues of $\mathbf{V}^*\mathbf{V}$. Given $\epsilon > 0$ let us denote by $G_N(\epsilon)$ the average number of eigenvalues less than or equal to ϵ, i.e.,

$$G_N(\epsilon) := \frac{1}{N}\mathbb{E}\Big(\Big|\big\{\lambda_i < \epsilon \,:\, i = 1, \ldots, N\big\}\Big|\Big).$$

Therefore, if there is an atom at zero for the measure μ with mass $\mu\{0\} = \beta$, the following holds

$$\inf_{\epsilon>0} \liminf_{N\to\infty} G_N(\epsilon) = \beta. \tag{6.1}$$

In Figure 3, we plot $G_N(10^{-p})$ as a function of p for $N = 1000$. These graphs suggest that if there is an atom its mass has to be smaller than 0.06. Further simulations suggest the absence of an atom at zero. However, at the moment, we are unable to prove this result.

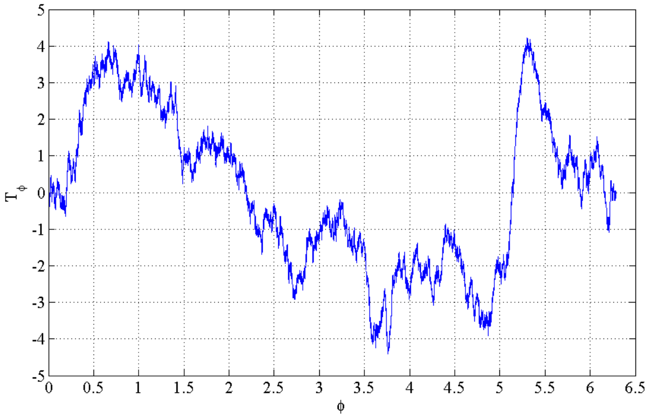

FIGURE 4. $T_N(\varphi)$ for 2^{15} dyadic rationals with $N = 10^6$.

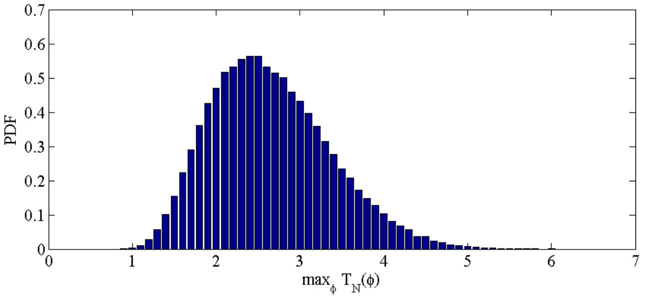

FIGURE 5. $\max_r T_{N,R}(\varphi_r)$ for 2^{15} dyadic rationals with $N = 32$ and 100,000 trials.

6.2. **Results for the Minimum Eigenvalue.** Our theoretical results show that the minimum eigenvalue is decreasing extremely fast. In Figure 4, we show a realization of T_N for a subset of the dyadic fractions and a large value of N, which indicates its qualitative behaviour. The maximum value over the values of φ selected is around 4. In Figure 5, we have obtained an empirical pdf for the above maximum. Finally, we show the results for $\max_r T_{N,R}(\varphi_r)$ when $R = 2^{15}$.

Finally, we present some numerical results for the behavior of the maximum of a random polynomial in the unit circle in the context of Theorem 9. In Figure 6, we show the graphs of $2 \log \max_{|z=1|} |P(z)|$ and $\sqrt{\gamma\pi}\epsilon\sqrt{N}/2$ as a function of N. This graph suggests that Theorem 9 could be slightly improved.

7. GENERALIZED RANDOM VANDERMONDE MATRIX

In this Section we present a generalized version of the previously discussed random Vandermonde matrices. More specifically, consider an increasing sequence of integers $\{k_p\}_{p=1}^{\infty}$ and let $\{\theta_1, \ldots, \theta_N\}$ be i.i.d. random variables uniformly distributed in the unit interval $[0, 1]$. Let $\mathbf{V}$ be the $N \times N$

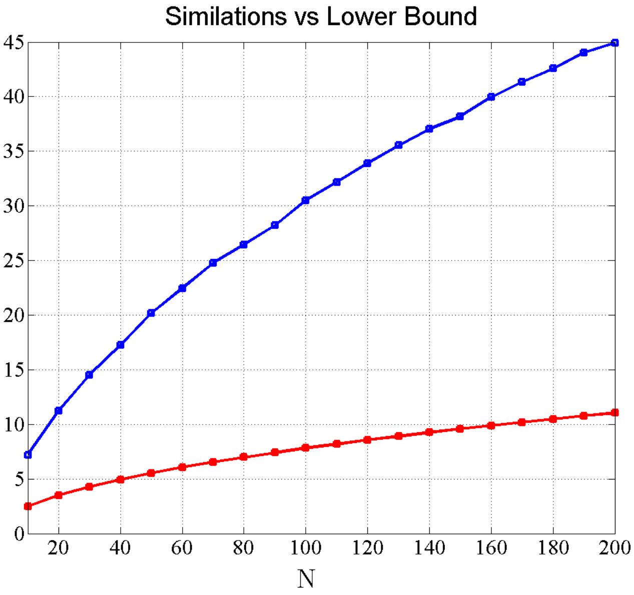

FIGURE 6. Graphs of the average of $2\log\max_{|z=1|}|P(z)|$ (blue) and $\sqrt{\gamma\pi\epsilon\sqrt{N}/2}$ (red) as a function of N where $2\log\max_{|z=1|}|P(z)|$ was averaged over 1000 realizations.

random matrix defined as

$$V(i,j) := \frac{1}{\sqrt{N}} z_j^{k_i} \tag{7.1}$$

where $z_j := e^{2\pi i\theta_j}$. Note that if we consider the sequence $k_p = p - 1$ then the matrix $\mathbf{V}$ is the usual random Vandermonde matrix defined in Equation (1.1). We are interested in understanding the limit eigenvalue distribution for the matrices $\mathbf{X} := \mathbf{V}\mathbf{V}^*$ and in particular their asymptotic moments. Let $r \geq 0$ and let us define the r-th asymptotic moment as

$$m_r := \lim_{N\to\infty} \mathbb{E}\Big[\mathrm{tr}_N(\mathbf{X}^r)\Big]. \tag{7.2}$$

These moments, as well as the limit eigenvalue distribution, depend on the sequence $\{k_p\}_{p=1}^{\infty}$.

Remark 2. *It is a straight forward calculation to see that $m_0 = m_1 = 1$, $m_2 = 2$ and $m_3 = 5$ no matter what is the sequence $\{k_p\}_{p=1}^{\infty}$. The first interesting case happens when r is equal to 4. These is because $r = 4$ is the first positive integer where there is a non-crossing partition, namely the partition $\rho = \{\{1,3\},\{2,4\}\}$.*

The next Theorem shows a combinatorial expression for the moments as well as the existence of the limit eigenvalue distribution.

Theorem 11. *Let $\{k_p\}_{p=1}^{\infty}$ be an increasing sequence of positive integers. Then*

$$m_r = \sum_{\rho\in\mathcal{P}(r)} K_\rho \tag{7.3}$$

where $\mathcal{P}(r)$ *is the set of partitions of the set* $\{1, 2, \ldots, r\}$ *and*

$$K_\rho := \lim_{N\to\infty} \frac{|S_{\rho,N}|}{N^{r+1-|\rho|}} \tag{7.4}$$

where $|\rho|$ *is the number of blocks of* ρ *and*

$$S_{\rho,N} := \Big\{(p_1, \ldots, p_r) \in \{1, 2, \ldots, N\}^r \,:\, \sum_{i\in B_j} k_{p_i} = \sum_{i\in B_j} k_{p_{i+1}}\Big\}, \tag{7.5}$$

where B_j *are the blocks of* ρ*. Moreover, there exists a unique probability measure* μ *supported in* $[0, \infty)$ *with these moments.*

Proof. Given $r \geq 0$ then

$$\begin{aligned} \operatorname{tr}_N(\mathbf{X}^r) &= \frac{1}{N} \sum_{(p_1,\ldots,p_r)} X(p_1, p_2)X(p_2, p_3)\ldots X(p_r, p_1) \\ &= \frac{1}{N^{r+1}} \sum_{(p_1,\ldots,p_r)} \sum_{(i_1,\ldots,i_r)} z_{i_1}^{(k_{p_1}-k_{p_2})} z_{i_2}^{(k_{p_2}-k_{p_3})} \ldots z_{i_r}^{(k_{p_r}-k_{p_1})}. \end{aligned}$$

The sequence $(i_1, i_2, \ldots, i_r) \in \{1, 2, \ldots, N\}^r$ uniquely defines a partition ρ of the set $\{1, 2, \ldots, r\}$ (we denote this by $(i_1, \ldots, i_r) \mapsto \rho$) where each block B_j consists of the positions which are equal, i.e.,

$$B_j = \{w_{j_1}, \ldots, w_{j_{|B_j|}}\}$$

where $i_{w_{j_1}} = i_{w_{j_2}} = \ldots = i_{w_{j_{|B_j|}}}$. Denote this common value by W_j. Then

$$\operatorname{tr}_N(\mathbf{X}^r) = \frac{1}{N^{r+1}} \sum_{(i_1,\ldots,i_r)\mapsto\rho} \sum_{(p_1,\ldots,p_r)} \prod_{k=1}^{|\rho|} z_{W_k}^{\sum_{i\in B_k}(k_{p_i}-k_{p_{i+1}})}. \tag{7.6}$$

Taking expectation on both sides we observe that

$$\mathbb{E}\left[z_{W_k}^{\sum_{i\in B_k}(k_{p_i}-k_{p_{i+1}})}\right] \neq 0$$

if and only if $\sum_{i\in B_k}(k_{p_i} - k_{p_{i+1}}) = 0$. Let $S_{\rho,N}$ be the r-tuples $(p_1, \ldots, p_r)$ which solve the equations

$$\sum_{i\in B_k} k_{p_i} = \sum_{i\in B_k} k_{p_{i+1}} \tag{7.7}$$

for all the the blocks $k = 1, 2, \ldots, |\rho|$ and let $|S_{\rho,N}|$ be its cardinality. Let K_ρ be defined as

$$K_\rho = \lim_{N\to\infty} \frac{|S_{\rho,N}|}{N^{r+1-|\rho|}}.$$

The it follows from Equation (7.6) that

$$m_r = \sum_{\rho\in\mathcal{P}(r)} K_\rho.$$

It is straight forward to see that the set of solutions of (7.7) has $r + 1 - |\rho|$ free variables since one of the equations is redundant (the sum of all the equations sums 0). Therefore, for every partition

ρ the value of K_ρ satisfies $0 \leq K_\rho \leq 1$. Then the moments are bounded by the Bell numbers $B_r = |\mathcal{P}(r)|$. Define,

$$\beta_r := \inf_{k \geq r} m_k^{\frac{1}{2k}} \leq B_k^{\frac{1}{2k}} \leq \inf_{k \geq r} \sqrt{k} = \sqrt{r}.$$

Hence, $\beta_r^{-1} \geq r^{-1/2}$ and therefore

$$\sum_{r=1}^{+\infty} \beta_r^{-1} = +\infty.$$

Therefore, by Carleman's Theorem [2] there exists a unique probability measure μ supported on $[0, +\infty)$ such that

$$m_r = \int_0^{+\infty} t^n \, d\mu(t).$$

In other words, the sequence m_r is *distribution determining.* ☐

Proposition 1. *Let $\rho \in \mathcal{P}(r)$ then $K_\rho = 1$ if and only if the partition ρ is non-crossing.*

The proof of this results follows similarly to the one presented in [17] for the sequence $k_p = p - 1$ and we leave it as an exercise for the reader.

Example 1. *Let $r = 4$ and let $\rho = \{\{1,3\},\{2,4\}\}$. Then*

$$K_\rho = \lim_{N\to\infty} \frac{|S_{\rho,N}|}{N^3}$$

where

$$S_{\rho,N} = \big\{(p_1,p_2,p_3,p_4) \in \{1,2,\ldots,N\}^4 \;:\; k_{p_1} + k_{p_3} = k_{p_2} + k_{p_4}\big\}.$$

For the case $k_p = p-1$ it was observed in [17] *that $K_\rho = 2/3$. As a matter of fact, it is not difficult to see that K_ρ is the volume of the polytope*

$$K_\rho = \mathrm{vol}\big(\{(x,y,z) \in [0,1]^3 \;:\; 0 \leq x + y - z \leq 1\}\big).$$

This polytope is shown in Figure 7. For the case $k_p = 2^p$ we see that

$$S_{\rho,N} = \big\{(p_1,p_2,p_3,p_4) \in \{1,2,\ldots,N\}^4 \;:\; 2^{p_1} + 2^{p_3} = 2^{p_2} + 2^{p_4}\big\}.$$

For positive integers $\{a,b,c,d\}$ the equation $2^a + 2^b = 2^c + 2^d$ holds if and only if $\{a,b\} = \{c,d\}$. Therefore, $|S_{\rho,N}| = 2N^2$ and hence $K_\rho = 0$.

The next Theorem shows that if $k_p = 2^p$ then the limit eigenvalue distribution is the famous Marchenko–Pastur distribution.

Theorem 12. *Let $k_p = 2^p$ then for every r and $\rho \in \mathcal{P}(r)$ the coefficient $K_\rho = 0$ if the partition is crossing. Hence*

$$m_r = |NC(r)|$$

the number of non-crossing partitions and μ is the Marchenko–Pastur distribution

$$d\mu(x) = \frac{1}{2\pi}\sqrt{\frac{4-x}{x}}\mathbf{1}_{[0,4]}.$$

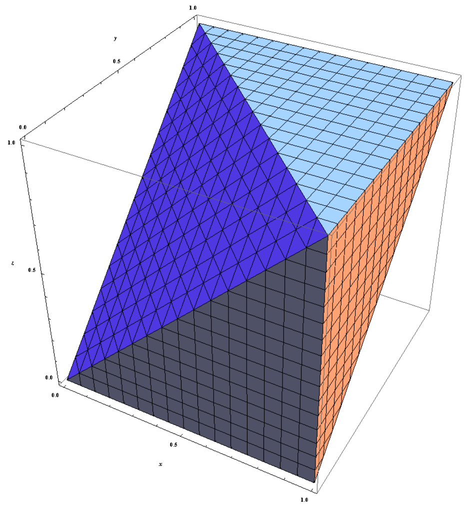

FIGURE 7. The polytope $(x, y, z) \in [0, 1]^3$ such that $0 \le x + y - z \le 1$.

Proof. We already observed that $K_\rho = 1$ iff the partition is non-crossing. Therefore, we need to show that for every crossing partition $K_\rho = 0$. Let $\rho \in \mathcal{P}(r)$ be a crossing partition with blocks $\{B_1, B_2, \ldots, B_{|\rho|}\}$. Let I be the set of indices such that for $i \in I$ the block B_i does not cross any other block B_j. Then we can decompose ρ as $\rho = \rho_1 \cup \rho_2$ where $\rho_2 = \cup_{i \in I} B_i$ is the union of all the non-crossing blocks. Then by the definition of K_ρ we see that $K_\rho = K_{\rho_1} K_{\rho_2}$. Now we need to show that $K_{\rho_1} = 0$. Up to a re-enumeration, if necessary, we see that $\rho_1 \in \mathcal{P}(s)$ where $s \le r$. By definition every block of ρ_1 crosses at least another block. For every n-tuples of positive integers $(a_1, \ldots, a_n)$ and $(b_1, \ldots, b_n)$ the equation

$$2^{a_1} + 2^{a_2} + \ldots + 2^{a_n} = 2^{b_1} + 2^{b_2} + \ldots + 2^{b_n}$$

implies that $\{a_1, \ldots, a_n\} = \{b_1, \ldots, b_n\}$. Hence, every equation in $S_{\rho_1,N}$ eliminates at least two variables and therefore $|S_{\rho_1,N}| = O(N^{s+1-2|\rho_1|})$. This implies that

$$K_{\rho_1} = \lim_{N \to \infty} \frac{|S_{\rho_1,N}|}{N^{s+1-|\rho_1|}} = 0$$

finishing the proof. $\square$

In Figure 8, we see the histogram of the matrix $\mathbf{V}\mathbf{V}^*$ for the sequence $k_p = 2^p$ and $N = 100$ over 1000 trials in comparison with the Marchenko–Pastur distribution. As it can be appreciated even for N as small as 100 the two are not to far apart. In Figure 9, we see the histogram of the eigenvalues of $\mathbf{V}\mathbf{V}^*$ for $k_p = p - 1$ and $N = 100$. The case $k_p = p^2$ is an interesting one (as well as the cases $k_p = p^a$). At the moment we don't understand what is the limit eigenvalue distribution for this sequence. For instance, is it true that $K_\rho = 0$ for every crossing partition? Is it true that $K_\rho = 0$ for the partition $\rho = \{\{1, 3\}, \{2, 4\}\}$? In a private communication with Prof. Carl Pomerance it was indicated that $|S_{\rho,N}|$ is of the order $O(N^2 \log(N))$. However, we are not providing a proof of this fact. In Figure 10, we show the values of $|S_{\rho,N}|/N^3$ as a function of N and we compare it with the case $k_p = 2^p$.

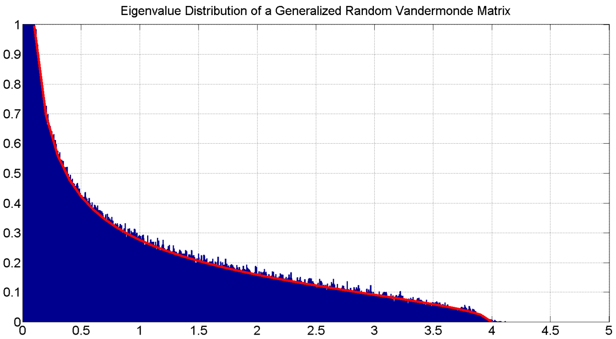

FIGURE 8. The blue graph is the histogram of eigenvalues of the matrix $\mathbf{V}\mathbf{V}^*$ for the sequence $k_p = 2^p$ and $N = 100$ over 1000 trials. The red curve is the Marchenko–Pastur distribution.

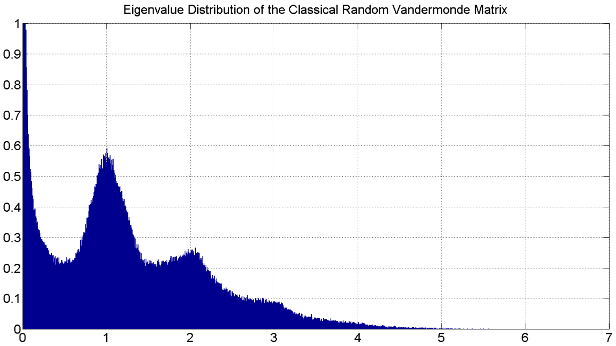

FIGURE 9. Histogram of the eigenvalues of matrix $\mathbf{V}\mathbf{V}^*$ for the sequence $k_p = p-1$ and $N = 100$ over 1000 trials.
